

Refugee Inflows and Native Parity Progression

Evidence from Turkey

Murat Güray Kırdar
Koç University

M. İkbâl Oruç
Koç University

SMTEA 2026 — May 9, 2026

1. Impact of immigration on native fertility is studied, but **not in the context of refugees**.
2. Fertility rates in OECD countries have fallen by half over the past 60 years to roughly **1.5 children per woman**.
3. **Turkey: a unique case study**
 - Host to one of the world's **largest refugee populations** (≈ 5.3 M Syrians registered, ≈ 3.6 M in Turkey).
 - Native total fertility now **below the OECD average** (≈ 1.41).
 - Ideal setting for studying how migration shocks interact with **low fertility**.

Main data source: 2013 & 2018 rounds of the TDHS.

- Nationally representative microdata on women with rich fertility histories.
 - Year of each birth, age at first cohabitation/marriage, migration history.
- **Pseudo-panel structure:** reconstructed annual marriage and birth histories for women from age 12 to survey date.

Main analytical sample: 2013/18 with **full controls and migration history** for both ever- and never-married women; province assigned by 2011 residence (pre-shock).

Four-wave (2003/08/13/18) ever-married sample used as a complementary specification — in appendix.

Reconstructing the Pseudo-Panel

Cross-sectional record (TDHS interview):

ID	Birth Yr	Childhood Prov	Move Yr	Dest. Prov	Birth 1	Birth 2
10001	1990	Adana	2009	Mardin	2010	2013

⇓ expanded into woman-by-year panel ⇓

Pseudo-panel:

ID	Age	Year	Province	Gave Birth 1	Gave Birth 2
10001	12	2002	Adana	0	0
⋮	⋮	⋮	⋮	⋮	⋮
10001	20	2010	Mardin	1	0
⋮	⋮	⋮	⋮	⋮	⋮
10001	23	2013	Istanbul	1	1
⋮	⋮	⋮	⋮	⋮	⋮
10001	28	2018	Istanbul	1	1

Cumulative parity outcomes (absorbing-state indicators):

$$Y_{ija}^{(p)} = \mathbb{1}\{\text{parity}_i \geq p \text{ by age } a\}, \quad p \in \{1, 2, 3, 4, 5\}, \quad a \in \{16, 20, 24, 28, 32, 36\}.$$

Plus marriage analogue $\mathbb{1}\{\text{ever married by age } a\}$.

Exposure: average refugee-to-native ratio over the woman's age window from 12 to a :

$$\bar{R}_{ja} = \frac{1}{a - 11} \sum_{s=12}^a R_{j, t(s,i)}.$$

Interpretation. A 1 pp. higher *average annual* ratio over ages 12– a raises $\Pr(\text{parity} \geq p \text{ by } a)$ by $\hat{\beta}^{(p,a)}$ pp.

Cohort variation. A 2013 woman observed at age 28 averages exposure over 1997–2013 (2 post-shock years); a 2018 woman observed at age 28 averages over 2002–2018 (7 post-shock years). Same age, same province, different $\bar{R}_{ja}$. Crossed with B_j , this cross-cohort variation in window timing is what the IV uses on top of FE.

- **Challenge: endogenous refugee location choice.**
 - Refugees may move toward provinces with better labor-market outcomes.
 - OLS may confound refugee exposure with local economic conditions that also affect fertility.
- **Quasi-exogenous variation.**
 - Early inflows were shaped by **border entry** and **government-run camps near Syria** (2011–2013).
 - This created a persistent **distance gradient**: provinces closer to the Syrian border received higher refugee exposure.
 - As refugees dispersed nationally over time, exposure varied across provinces in a way strongly predicted by **geographic proximity**.

Province-year instrument (Aksu, Erzan and Kırdar 2022):

$$Z_{n,t} = \sum_{s=1}^{13} \underbrace{\left[\frac{(1/d_{s,T}) \pi_s}{\sum_{X \in \{T,L,J,I\}} (1/d_{s,X})} \right]}_{\text{share weight (time-invariant)}} \cdot \frac{T_t}{d_{n,s}}$$

π_s pre-war pop. share of Syrian province s ; $d_{s,X}$ distance from s to host $X \in \{T, L, J, I\}$; $d_{n,s}$ distance from s to Turkish province n ; T_t aggregate Syrian refugee stock across the four host countries.

Key decomposition — only T_t varies in time:

$$Z_{n,t} = B_n \times T_t, \quad \bar{Z}_{ja} = B_j \times \bar{T}_a.$$

$\implies$ **Continuous-treatment difference-in-differences**: B_n assigns province intensity (geography), T_t activates the shock after 2011.

Settlement-Propensity Weight B_n

Settlement-propensity weight B_n across Turkish provinces (quintiles)

Estimating Equation

For each (p, a) separately,

$$Y_{ija}^{(p)} = \alpha + \beta^{(p,a)} \bar{R}_{ja} + X_i' \Gamma + \delta_j + \mu_{t(a,i)} + \theta_{g(j)} \cdot t(a, i) + \lambda_{l(i)} \cdot t(a, i) + \varepsilon_{ija},$$

with $\bar{R}_{ja}$ instrumented by $\bar{Z}_{ja} = B_j \times \bar{T}_a$.

- $\beta^{(p,a)}$ — coefficient of interest: effect of a 1 pp. higher *average annual* refugee-to-native ratio on $\Pr(\text{parity} \geq p \text{ by age } a)$.
- X_i' — individual controls: survey wave, childhood urban/rural, mother's education, mother tongue.
- δ_j — province FE; $\mu_{t(a,i)}$ — year-at-age- a FE ($\equiv$ birth-cohort FE at fixed a).
- $\theta_{g(j)} \cdot t$ — **five-region**-specific linear time trends.
- $\lambda_{l(i)} \cdot t$ — **mother-tongue**-specific linear time trends (Turkish / Kurdish / Arabic).
- Trends start in 1987; SEs clustered at province; DHS sampling weights.

Why Region-Specific Trends? — The 5-Region Scheme

Five-region scheme used for region-specific time trends

Why Mother-Tongue-Specific Trends?

Pre-shock cohorts only. **Levels and trends differ sharply** across MT groups — and Region 5 (high B_n) is **55% Kurdish**-speaking versus 1.7–12% in regions 1–4. So B_n correlates with MT composition by geography, and MT-specific trends are needed to absorb the differential transition.

Placebo: $Y \sim B_n \times t$ on Pre-Shock Cohorts (BH-FDR)

Outcome	Age 16	Age 20	Age 24	Age 28	Age 32	Age 36

Observations	3,145	2,785	2,415	1,951	1,489	1,055

Sharp signal among Kurdish/Arabic women at higher parities and late 20s/30s. Turkish-speaking women effectively null (**Turkish**).

Heterogeneity III — Lower-Educated Women ($\leq$ middle school), BH-FDR

Outcome	Age 16	Age 20	Age 24	Age 28	Age 32	Age 36
Ever Married	-0.1848 (0.3031)	-0.8722 (1.2854)	2.0480 (1.8239)	-0.0590 (1.5294)	0.1893 (1.0346)	-0.2025 (1.1901)
Parity ≥ 1	-0.0234 (0.1870)	0.0484 (1.2489)	0.2907 (2.4427)	1.3034 (1.9572)	0.0446 (1.2737)	0.5583 (1.3313)
Parity ≥ 2	0.0029 (0.0571)	0.2609 (1.6357)	-1.1164 (1.6824)	1.6909 (1.6453)	1.6018 (2.7430)	1.9856 (1.6354)
Parity ≥ 3	0.0038 (0.0069)	0.7375 (0.7647)	-0.6375 (1.2099)	2.8227 (2.2384)	3.2607 (2.4464)	4.6894** (1.6967)
Parity ≥ 4	— (—)	— (—)	-0.0667 (0.6786)	3.1747* (1.2937)	2.9678** (1.0527)	6.6579** (2.3695)
Parity ≥ 5	— (—)	— (—)	0.3507 (0.4137)	1.7869 (1.2837)	1.8934 (1.1604)	5.6194** (1.8604)
Observations	9,361	9,132	8,729	7,633	6,348	4,897

Effect concentrated in **lower-educated** women at higher parities and late 20s/30s. High-education women null (**high educ**). **Common thread across heterogeneity:** effects appear in **higher-baseline-fertility** groups where there is room to move up the parity ladder.

- **Labor-market / opportunity-cost mechanism** (Aksu, Erzan and Kirdar 2022):
 - Refugee inflows displace native women's jobs disproportionately — informal-sector substitution.
 - Lower native female employment $\Rightarrow$ **lower opportunity cost of childbearing** relative to work.
 - Predicts a shift in marriage timing and parity progression for women whose labor-supply margin is most affected.
- **Social-norm / preference-shift mechanism:**
 - Large demographic shocks can change perceived returns to marriage and fertility, or shift local norms about family size.
 - Potentially strongest in regions with high refugee exposure and among groups with **early-marriage and high-fertility norms**.
 - Testable implication: a shift in *stated* fertility preferences (ideal n) at the same parities where realised fertility responds.

Social-Norm Mechanism: Stated Fertility Preferences (Ideal n)

Outcome. $\mathbb{1}\{\text{ideal number of children} \geq k\}$ for $k \in \{2, 3, 4, 5\}$, asked at survey.

Spec. Cross-sectional 2SLS, four-wave EM sample, current-year exposure.

Outcome	Ideal $n \geq 2$	Ideal $n \geq 3$	Ideal $n \geq 4$	Ideal $n \geq 5$
$\bar{R}_{j(i),t(i)}$	0.0458 (0.0605)	0.1739 (0.2536)	0.5142* (0.2700)	0.2555** (0.1087)
Observations	14,775	14,775	14,775	14,775

A shift in *stated* ideal family size at the upper thresholds (≥ 4 , ≥ 5) is hard to rationalise as a pure labor-market response — a labor-supply shock changes *behavior*, not *desired* family size. The pattern is more naturally read as a **preference / norm shift**, sharper in the same subgroups where realised fertility responds ([subgroup tables](#)).

The Syrian inflow raised native parity progression in groups with higher baseline fertility.

- Pooled effects positive at higher parities, late 20s/30s; no cell survives BH-FDR across 32 tests.
- Under BH-FDR, signal concentrates in three heterogeneity dimensions where the pooled raw signal originates: **heavily-treated southeast**, **Kurdish/Arabic** mother-tongue women, and **lower-educated** women.
- Stated **ideal- n** shifts up at the same upper thresholds, sharper in the same subgroups.
- Marriage and first births unaffected everywhere.

Mechanism. Pattern is consistent with both a **labor-market / opportunity-cost** channel (refugee inflows reduce female employment in the affected groups, lowering the cost of additional children) and a **social-norm / preference-shift** channel (the shift in stated ideal- n at the same parities). Disentangling the two is ongoing work.

Thank you. / Questions?

Appendix

Appendix: B_n vs Kurdish/Arabic Share at Province Level

Each dot is one province. Provinces with high B_n are also those with high Kurdish/Arabic shares — motivating the MT-specific trend control.

[← Back](#)

Primary sample:

	Age 16	Age 20	Age 24	Age 28	Age 32	Age 36
First-stage F	43.93	131.31	102.39	43.72	52.90	143.70
Observations	14,354	13,484	12,241	10,240	8,245	6,110

Four-wave (EM) sample:

	Age 16	Age 20	Age 24	Age 28	Age 32	Age 36
First-stage F	29.40	32.91	51.24	43.49	53.01	83.21
Observations	19,281	21,525	21,782	19,776	16,442	12,282

Appendix: Decomposition Ladder — 4 Rungs

The four-wave specification differs from the primary in three ways. We isolate each by running the IV on four nested samples:

	Waves	Sample	Province	Isolates
(i)	2013/18	Full	2011 res.	primary
(ii)	2013/18	Ever-married	2011 res.	EM-restriction (i)→(ii)
(iii)	2013/18	Ever-married	Childhood	Childhood-prov. ME (ii)→(iii)
(iv)	2003/08/13/18	Ever-married	Childhood	Added-waves (iii)→(iv)

Tables on the next four slides — fertility outcomes only.

Appendix: Decomposition Rung (i) — Primary, raw
